CSE6140/CX4140 Spring 2025 Project Minimum Set Cover problem

March 10, 2025

1 Overview

The Minimum Set Cover problem is a well known NP-complete problem. In this project, we will treat the problem using different algorithms, evaluating their theoretical and experimental complexities on real world datasets.

2 Objectives

- Get hands-on experience in solving an intractable problem that is of practical importance
- Implement an exact branch-and-bound algorithm
- Implement approximate algorithms that run in reasonable time and provide high-quality solutions with guarantees
- Implement heuristic algorithms (without approximation guarantees)
- Develop your ability to conduct empirical analysis of algorithm performance on datasets, and to understand the trade-offs between accuracy, speed, etc., across different algorithms
- Develop teamwork skills while working with other students

3 Groups

You will be in a group of up to 4 students. We encourage you to form your own groups, and use Piazza as a resource. Afterwards, please designate one member per group to complete the assignment "Group and programming language submission for project" through Canvas by **Mar. 26**, **Wednesday**, **11:59pm**: In the text entry, put each student's last name and first name per line, followed by the programming language (Python, C/C++ or Java) your group will use. For instance:

Cheng, Yuqi

Devaramani, Rajeshwari

Du, Kangrui

Liu, Xuanzhang

Python

Note that if your team has less than 4 students, we may add students to your team. Also, rubrics will be the same for all teams, regardless of the number of members in each team.

4 Background

Let

$$U = \{x_1, x_2, \dots, x_n\}$$

be a universe and

$$S = \{S_1, S_2, \dots, S_m\}$$

be a collection of subsets of U (i.e., $S_i \subseteq U$ for all i = 1, ..., m). The minimum set covering problem is to select a minimal subcollection

$$T \subseteq S$$

such that

$$\bigcup_{S_i \in T} S_i = U.$$

In other words, select minimal number of S_i so that every element $x_i \in U$ must appear in at least one of your chosen S_i . For more details on the Minimum Set Cover problem, refer to Karp's original 21 NP-Complete problems https://cgi.di.uoa.gr/~sgk/teaching/grad/handouts/karp.pdf.

5 Algorithms

Your team will implement **four** algorithms that fall into three categories:

- 1. Exact branch-and-bound solution to the problem. The naive solution would be to enumerate whether to choose or not for all subsets S_i then verify all individual solutions. Is there a way to explore the sub-structures in a more efficient manner by bounding solutions? How do we derive a reasonable lower / upper bound?
- 2. Approximation algorithm with approximation guarantees. Please implement an approximation algorithm for the Minimum Set Cover with approximation guarantees of $O(\log n)$.
 - Hint: There is a simple and intuitive greedy algorithm that heuristically chooses a subset until U is covered and can achieve an approximation of $O(\log n)$. Can you come up with such an algorithm?
- 3. Local Search. There are many variants of local search (LS) and you are free to select which one you want to implement. Please implement 2 types/variants of local search. They can be in different families of LS such as Simulated Annealing vs Hill Climbing, or they can be in the same general family but should differ by the neighborhood they are using, or by the perturbation strategy, etc.

Hint: While local search does not guarantee the convergence of solutions, most of the time it should converge relatively quickly given a good search space. How do you formulate the search space such that the exploration is efficient and doesn't get stuck? This can have a night-and-day difference in simulated annealing or hill climbing algorithms.

6 Data

You will run the algorithms you implement on some real and random datasets, which will be available on Canvas: data.zip under assignment "Project".

This dataset comprises three sections. The first section is the test dataset, which includes problems alongside their optimal selections. These solutions serve as a benchmark to verify the correctness of your code. The remaining two sections consist of datasets of varying sizes: *small* datasets and *large* datesets, respectively. Both of these datasets provide only the optimal values for input instances, without the optimal set of subsets selected. These optimal values can be used to assess the accuracy of your code by comparing your solutions against these optimal values.

For each instance, the data is structured as follows:

Input Format: The first row of input file consists of 2 integers separated by space, indicating the number of items n and the number of subsets m respectively. Subsequent m rows then provide the information of each subset. The (i+1)-th row, which has $|S_i|+1$ integers separated by spaces, denotes subset S_i . Each row begins with a positive integer $|S_i|$, followed by $|S_i|$ integers $x_1, x_2, ..., x_{|S_i|} (1 \le x_j \le n)$ representing the items in S_i . An example is shown below.

Table 1: Dataset Description

Set	Number of Problems	n	m	Names	
Test	5	3-10	3-10	test#.in, test#.out	
Small Scale	18	≤20	≤20	small#.in, small#.out	
Large Scale	12	≤2000	≤2000	large#.in, large#.out	

Reference Output Format: The first row of the reference output is a single integer *ans* denoting the optimal answer. The second line will be only for test#.out, listing the indices of all the subsets been chosen.

Example Input	Example Output			
5 7	2			
1 5	3 7			
11				
2 4 5				
1 5				
1 4				
3 1 2 4				
3 1 2 3				

7 Code

All your code files should include a top comment that explains what the given file does. Your algorithms should be well-commented and self-explanatory. Use a README file to explain the overall structure of your code, as well as how to run your executable.

Your executable should take as input i) the filename of a dataset and ii) the cut-off time (in seconds) iii) the method to use, iv) a random seed. If it is run with the same 4 input parameters, your code should produce the same output. The executable must conform with the following format:

exec -inst <filename> -alg [BnB|Approx|LS1|LS2] -time <cutoff in seconds> -seed <random seed>

Any run of your executable with any four inputs (filename, cut-off time, method and seed) must produce two types of output files:

1. Solution files:

- File name: $< instance > _ < method > _ < cutoff > _ < randSeed > *.sol$, e.g. $example_BnB_600.sol$, $example_LS1_600_4.sol$ Note that as in the example above, randSeed is only applicable when the method of choice is randomized (e.g. local search). When the method is deterministic (e.g. branch-and-bound), randSeed is omitted from the solution file's name.
- File format:
 - (a) line 1: quality (the minimal size of subset collection) of best solution found (integer)
 - (b) lines 2: list of index of the subsets selected (space-separated): $i_1 i_2 \cdots i_n$

2. Solution trace files:

- File name: $<instance>_{-}<method>_{-}<cutoff>_{-}<randSeed>*.trace,$ e.g. $example_BnB_600.trace$, $example_LS1_600_4.trace$. Note that randSeed is used as in the solution files.
- File format: each line has two values (space-separated):
 - (a) A timestamp in seconds (double)
 - (b) Quality of the best found solution at that point in time. Note that to produce these lines, you should record every time a new improved solution is found.

(c) Trace files are not required for approximation algorithms but are required for BnB and local search algorithms.

An example:

 $0.22\ 30$

 $1.11\ 19$

3.99 17

8 Output

You should run all the algorithms you have implemented on all the instances we provide, and submit the output files generated by your executable, as explained in the Code section.

P.S.: DO NOT SUBMIT THE INPUT DATA FILES.

9 Report

9.1 Formatting

You will use the format of the Association for Computing Machinery (ACM) Proceedings to write your report. See http://www.acm.org/publications/proceedings-template for LaTeX and Word downloads. You can choose any template on this website.

9.2 Content

Your report should be written as if it were a research paper in submission to a conference or journal. If you use an algorithm that you find in a paper or online resources, please cite these resources. A sample report outline looks like this:

- Abstract.
- Introduction: a short summary of the problem, the approach and the results you have obtained.
- Problem definition: a formal definition of the problem.
- Related work: a short survey of existing work on the same problem, and important results in theory and practice.
- Algorithms: a detailed description of each algorithm you have implemented, with pseudo-code, approximation guarantee (if any), time and space complexities, etc. What are the potential strengths and weaknesses of each type of approach? Did you use any kind of automated tuning or configuration for your local search? Why and how you chose your local search approaches and their components? Please cite any sources of information that you used to inform your algorithm design.
- Empirical evaluation: a detailed description of your platform (CPU, RAM, language, compiler, etc.), experimental procedure, evaluation criteria and obtained results (plots, tables, etc.). What is the lower bound on the optimal solution quality that you can derive from the results of your approximation algorithm and how far is it from the true optimum? How about from your branch-and-bound?
- Discussion: a comparative analysis of how different algorithms perform with respect to your evaluation criteria, or expected time complexity, etc.
- Conclusion

9.3 Evaluation

We now describe how you will use the outputs produced by your code in order to evaluate the performance of the algorithms.

1. Comprehensive Table: Include a table with columns for each of your Set Cover algorithms as seen below. For all algorithms report the relative error with respect to the optimum solution quality provided to you in the Set Cover instance files. Relative error (RelErr) is computed as (Alg-OPT)/OPT where Alg is the answer of your algorithm. Round time and RelErr to two significant digits beyond the decimal. For local search algorithms, your results for each cell should be the average of some number (at least 10) of runs with different random seeds for that dataset. You will fill in average time (seconds) and average total value. You can also report in any other information you feel is interesting. The comprehensive table should include results of all the instances of "large#" and "small#". It's optional to include instances from "test#".

	Branch and Bound			Etc. (other algorithms)		
Dataset	Time (s)	collection size	RelErr	Time (s)	total value	RelErr
small1	1.14	5	0	0.25	6	0.2

Branch-and-Bound algorithms can take a long time on large instances. You can use the quality of your solution from the approximation algorithm as the initial upper bound, which is much tighter than a naive upper bound. You can set a time limit of a few minutes which allows you to get some solution that is better than your initial upper bound.

The next three evaluation plots are applicable to local search algorithms only, and need only be presented for the instances "large1" and "large10". All the information you need to produce these plots is in your solution trace files.

- 1. Qualified Runtime for various solution qualities (QRTDs): A plot similar to those in Lecture on Empirical Analysis. The x-axis is the run-time in seconds, and the y-axis is the fraction of your algorithm runs that have 'solved' the problem. Note that 'solve' here is w.r.t. to some relative solution quality q^* . For instance, for $q^* = 0.8\%$, a point on this plot with x value 5 seconds and y value 0.6 means that in 60% of your runs of this algorithm, you were able to obtain a total value of at most the optimal value minus 0.8% of that. When you vary q^* for a few values, you obtain the points similar to those shown in the lecture.
- 2. Solution Quality Distributions for various run-times (SQDs): Instead of fixing the relative solution quality and varying the time, you now fix the time and vary the solution quality. The details are analogous to those of QRTDs.
- 3. Box plots for running times: Since your local search algorithms are randomized, there will be some variation in their running times. You will use box plots, as described in the 'Theory' section of this blog post: http://informationandvisualization.de/blog/box-plot. Read the blog post carefully and understand the purpose of this type of plots. You can use online box plot generators such as http://boxplot.tyerslab.com/ to produce the plot automatically from your data.

10 Deliverables

Failure to abide by the file naming and folder structure as detailed here will result in penalties. Only "one" student from each group should submit the following:

- 1. A PDF file of the report following the guidelines in section 9. The report should be submitted to Gradescope, Assignment "CourseProject-report".
- 2. A zip file of the following files/folders:

- Code: a folder named 'code' that contains all your code, the executable and a README file, as explained in section 7.
- Output: a folder named 'output' that contains all output files, as explained in section 7.

The zip file should be submitted to Gradescope, Assignment "CourseProject-zip".

11 Team Evaluation

Each student should also submit a *private* evaluation of their team members. This assignment will be announced later, close to the finish of the project. For each team member (including self) include a score from 1 to 9 (scores for all team members should sum up to 10), outline the contributions that the member did to the project, and justification for the score. You can skip this assignment if you think all team members have contributed equally.
